# Predicting structural material degradation in advanced nuclear reactors with ion irradiation

Stephen Toller<sup>1,2,✉</sup>, Gerrit VanCoevering<sup>1</sup>, Brian D. Wirth<sup>3</sup> & Gary S. Was<sup>1</sup>

Swelling associated with the formation and growth of cavities is among the most damaging of radiation-induced degradation modes for structural materials in advanced nuclear reactor concepts. Ion irradiation has emerged as the only practical option to rapidly assess swelling in candidate materials. For decades, researchers have tried to simulate the harsh environment in a nuclear reactor in the laboratory at an accelerated rate. Here we present the first case in which swelling in a candidate alloy irradiated ~2 years in a nuclear reactor was replicated using dual ion irradiation in ~1 day with precise control over damage rate, helium injection rate, and temperature and utilize physical models to predict the effects of radiation in reactors. The capability to predict and replicate the complex processes surrounding cavity nucleation and growth across many decades of radiation dose rate highlights the potential of accelerated radiation damage experiments. More importantly, it demonstrates the capability to predict the swelling evolution and the possibility to predict other features of the irradiated microstructure evolution that control material property degradation required to accelerate the development of new, radiation-tolerant materials.

The continued contribution of nuclear power to carbon-free electricity generation will require the development of more efficient advanced reactors while maintaining safety and security. These advanced reactor designs impose harsher environments of higher temperatures and more intense radiation fields than current light water reactors and necessitate accelerated materials development to ensure components withstand radiation-induced degradation<sup>1</sup>. Reactor irradiation campaigns to understand radiation effects on microstructure and properties take years to complete, are extremely expensive, and hampered by the paucity of test reactors, all of which contribute to the historical problem of a glacial pace of research to assess candidate materials. For decades, researchers, individual laboratories and international organizations<sup>2–4</sup> have been searching for methods and theory to accelerate radiation damage in structural materials for nuclear energy applications to speed the development of new, more radiation resistant materials. Ion irradiation offers the capability to shrink the irradiation time from many years in a reactor to days using an accelerated damage rate to predict microstructure and mechanical property changes at lower cost<sup>5,11,12</sup>. Therefore, ion irradiation is the only viable means to study many damaging degradation processes that could limit component lifetime, such as irradiation-induced swelling.

The dimensional instability from swelling can cause operational tolerances to be quickly exceeded and arises from cavities in irradiated materials<sup>13</sup> as observed and the subject of further research<sup>2,11–14</sup>. Cavity nucleation depends on the coalescence of defects generated from irradiation damage. The generation of gases by transmutation, such as helium, stabilizes cavity embryos and results in bubble formation, further complicating the nucleation process, which also depends on the crystal structure and alloy microstructure. Ion irradiation can simulate the reactor environment by creating damage with self-ions while simultaneously injecting helium as a surrogate for transmutation. The high damage rates (quantified as displacements per atom per second, dpa/s) accessible with ion irradiation ( $10^{-4}$  to  $10^{-1}$  dpa/s) compresses the irradiation time by about three orders of magnitude. Yet for accelerated irradiations to be a useful tool for studying and qualifying nuclear materials, the roles and interdependencies of damage rate, helium content, and irradiation temperature on cavity nucleation and growth, along with the radiation-damaged microstructure, must be understood predictively.

This paper identifies the underlying processes governing cavity nucleation and early stage growth in a ferritic-martensitic steel, T91, neutron irradiated in the BOR-60 reactor<sup>15</sup> at a dose rate between  $6 \times 10^{-7}$  dpa/s and  $9 \times 10^{-7}$  dpa/s to doses between 15 and 35 dpa at 376–524 °C and applies that understanding to successfully
