What is Diabetes?

Diabetes is a group of metabolic diseases characterized by a chronic disturbance in the blood glucose levels. In diabetes, the body does not produce enough insulin or the insulin it produces does not work properly. Insulin helps the body use glucose for energy and to store extra glucose for later use.

Types of Diabetes

There are three main types of diabetes: Type 1, Type 2, and Gestational Diabetes. Type 1 is an autoimmune disease where the body's immune system attacks the insulin-producing cells in the pancreas. Type 2 is a chronic condition where the body's cells become resistant to insulin. Gestational Diabetes is a temporary condition that develops during pregnancy.

What is Insulin?

Insulin is a hormone produced by the pancreas that helps the body use glucose. It allows the glucose to enter the cells and be used for energy. Without insulin, glucose cannot enter the cells and the body's cells starve for energy.

The liver takes up glucose, converts it into glycogen and stores it.

Glucose signals the liver to convert glycogen to glucose and release the glucose into the blood.

The conversion of glycogen into glucose is called gluconeogenesis and occurs in the liver and kidneys.

Type 1 Diabetes: In this condition, the body does not produce enough insulin. This is because the immune system attacks and destroys the insulin-producing cells in the pancreas. This leads to a deficiency of insulin, which causes the blood glucose levels to rise.

Type 2 Diabetes: In this condition, the body does not use insulin properly. This is because the cells in the body become resistant to insulin. This leads to a relative deficiency of insulin, which causes the blood glucose levels to rise.

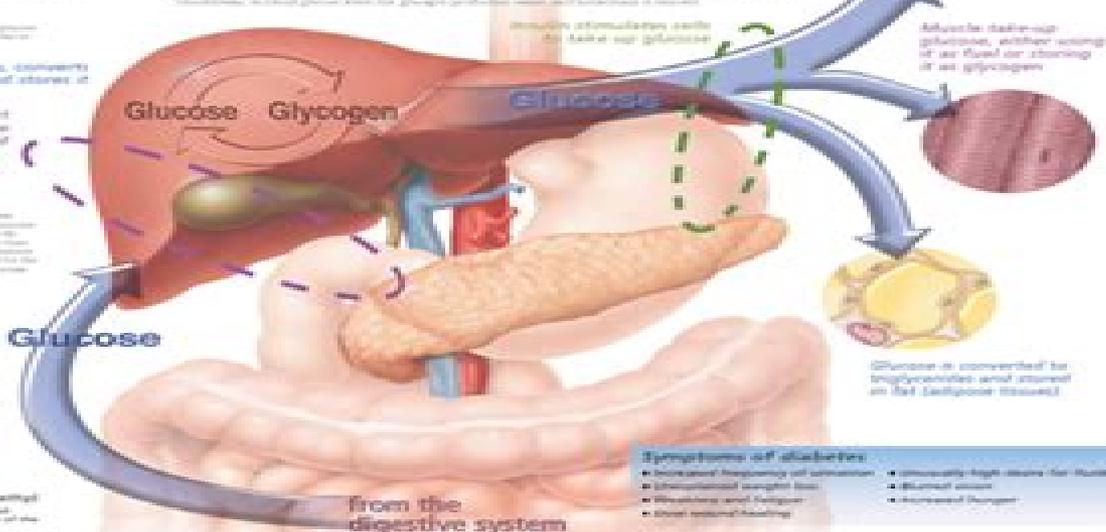

What is Glucose?

Glucose is a type of sugar and is the body's main source of energy. It is produced in the liver and is used by the body for energy. It is also stored in the liver and muscles for later use.
