

Understanding Diabetes

What is Diabetes?

Diabetes is a group of metabolic diseases characterized by a chronic disturbance in the blood glucose levels. In diabetes, the body does not produce enough insulin, or the insulin it produces does not work properly. Insulin is a hormone that allows glucose to enter the cells to be used for energy.

Types of Diabetes

There are three main types of diabetes: Type 1, Type 2, and Gestational Diabetes. Type 1 is an autoimmune disease where the body's immune system attacks the insulin-producing cells in the pancreas. Type 2 is a lifestyle-related disease where the body becomes resistant to insulin. Gestational Diabetes is a temporary condition that occurs during pregnancy.

What is Insulin?

Insulin is a hormone produced by the pancreas that allows cells to absorb glucose. It acts as a key that unlocks the cells so that glucose can enter and be used for energy. Without insulin, glucose cannot enter the cells, leading to high blood sugar levels.

The liver takes up glucose, converts it into glycogen and stores it.

Glucose signals the liver to convert glycogen to glucose and release the glucose into the blood.

The conversion of glycogen into glucose is called gluconeogenesis and occurs in the liver and kidneys.

Type 1 Diabetes: In this condition, the body does not produce enough insulin. This is an autoimmune disease where the immune system attacks the insulin-producing cells in the pancreas. Type 1 diabetes is usually diagnosed in children and young adults.

Type 2 Diabetes: This condition occurs when the body does not use insulin effectively. It is often associated with obesity and a sedentary lifestyle. Type 2 diabetes is usually diagnosed in middle-aged and older adults.

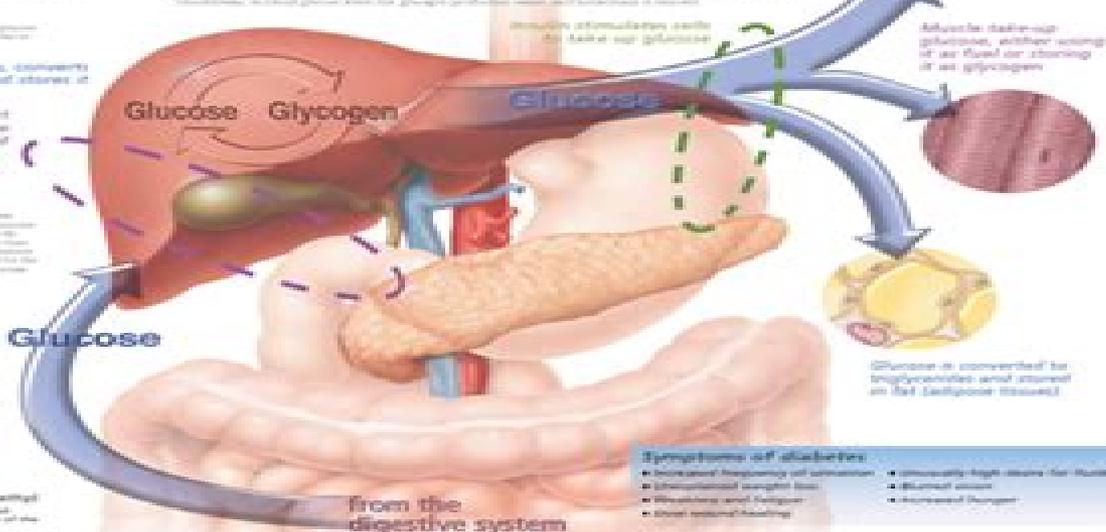

What is Glucose?

Glucose is a type of sugar and is the body's main source of energy. It is produced in the liver and is transported in the blood to the cells. Cells use glucose as fuel to produce energy.

Glucose Metabolism

Glucose metabolism is the process by which the body uses glucose for energy. It involves the conversion of glucose into pyruvate, which is then either used for energy or stored as glycogen or fat. The liver plays a central role in glucose metabolism, storing glucose as glycogen and releasing it into the blood when needed.
