Life Science 454 platform is presented and aspects of the process that can introduce variability in data are identified Four ecological data sets that were generated by the 454 platform are used for illustration Characteristics of these data include high dimensionality a large proportion of zeros usually in excess of 90% and nonzero values that are strongly right skewed A nonparametric method to standardize these data is presented and effects of standardization on outliers and skewness are examined Traditional statistical methods for analyzing macroscopic species abundance data are discussed and the applicability of these methods to microscopic species data is examined One objective that receives focus is the classification of microscopic species as either rare or common species This is an important distinction since there is much evidence to suggest that the biological and environmental mechanisms that govern common species are distinctly different than the mechanisms that govern rare species This indicates that the abundance patterns for common and rare species may follow different probability models and the suitability of the Pareto distribution for rare species is examined Techniques for classifying macroscopic species are shown to be ill suited for microscopic species and an alternative technique is presented Recognizing that the structure of the data is similar to that of financial applications such as insurance claims and the distribution of wealth the Gini index and other statistics based on the Lorenz curve are explored as potential test statistics for distinguishing rare versus common species
