Distributed Synchronization of Parallel Programs Patrice Quinton, Jean-Pierre Verjus, 1986 Distributed Synchronization of Parallel Programs: why and How? Institut National de Recherche en Informatique et en Automatique, P. Quinton, Jean-Pierre Verjus, 1986 *Compiler Analysis to Implement Point-to-point Synchronization in Parallel Programs*

John Nguyen, 1993 Abstract The shared memory data parallel model presents an attractive interface for programming multiprocessors by allowing for easy management of parallel tasks while hiding details of the underlying machine architecture Unfortunately the shared memory abstraction requires synchronization in order to maintain data consistency Present compilers provide consistency between parallel code sections by enforcing a global point of synchrony with a barrier synchronization Such a simple mechanism possesses several disadvantages First the required global collection of information generates significant overhead which leads machine designers to employ special hardware to support barriers Second global synchronization reduces parallelism by requiring needless serialization of independent tasks This work aims to reduce the costs associated with these disadvantages by generating pairwise point to point synchronization between specific tasks Implementation of point to point synchronization demands extensive analysis of program dependences A compiler must perform flow analysis and dependence testing in order to compute lexical dependences between program statements In addition dynamic dependences between processors must be computed by examining array reference and statement contexts The final synchronization scheme must support any dependences that arise in the program while ensuring that no deadlock scenarios can occur This work proposes algorithms that satisfy such requirements and presents some encouraging results from a preliminary implementation

On Synchronization Patterns in Parallel Programs Jean-Loup Baer, Richard N. Zucker, 1991 Abstract Efficient synchronization is a key element in obtaining good speed up from parallel programs The overhead introduced by synchronization especially lock manipulation can sometimes remove any benefit from parallelizing programs Techniques to efficiently obtain locks under high contention have been studied in the literature using artificial programs We consider the impact of these techniques in a more realistic framework using a sample of real parallel programs running on a shared bus multiprocessor system Cycles lost to lock contention and the number of processors waiting to acquire a lock are the two principal metrics that we use Trace driven simulation experiments are performed for sequentially consistent and weakly consistent architectural models

Static Analyses and Optimizations for Parallel Programs with Synchronization Yuan Zhang, 2008 As parallel systems become dominant in computer architectures parallel programs that take the advantage of multiple threads of control are taking the place of conventional sequential programs Yet parallel programs have introduced

new challenges to compiler static analyses and optimizations. On one hand, classical compiler analyses and optimizations need to be enhanced to handle the inter-thread interference and synchronization-enforced dependence relation in a parallel program. On the other hand, new analyses and optimizations need to be designed for new programming language features. In this dissertation, we propose the following compiler static analyses and optimizations for parallel programs with synchronization:

1. An interprocedural multi-valued expressions analysis for both distributed and shared memory programs based on program slicing. An expression is multi-valued if it evaluates differently in different threads. For Single Program Multiple Data style programs, multi-valued expressions analysis is a key component to determine the concurrent paths which are executed by different threads concurrently.
2. An interprocedural barrier matching technique for both distributed and shared memory programs to detect synchronization errors caused by the misplacement of barriers or if the program is validated to determine the set of barrier statements that synchronize together.
3. The first interprocedural concurrency analysis algorithm that can handle shared memory programs with textually unaligned barriers.
4. A new framework of flow-sensitive and synchronization-sensitive data flow analyses for shared memory programs. Pointer analysis is used as an example to demonstrate the effectiveness of this framework. The most significant advantage of this framework is that inter-thread interference and synchronization-enforced dependence are modeled as concurrency relations; thus, it is easily extensible to new language features and compatible with different memory models.
5. A lock assignment algorithm to optimize shared memory programs with atomic sections: a high-productivity synchronization construct that enforces atomicity and mutual exclusion. Taking a program annotated with atomic sections, the compiler automatically infers an assignment of the minimum number of locks to atomic sections so as to exploit the parallelism among atomic sections without violating their semantics. Two additional lock optimization problems that are closely related to the lock assignment problem are presented.

Synchronization Costs in Parallel Programs and Concurrent Data Structures Vitalii Aksenov, 2018. To use the computational power of modern computing machines, we have to deal with concurrent programs. Writing efficient concurrent programs is notoriously difficult, primarily due to the need of harnessing synchronization costs. In this thesis, we focus on synchronization costs in parallel programs and concurrent data structures. First, we present a novel granularity control technique for parallel programs designed for the dynamic multithreading environment. Then, in the context of concurrent data structures, we consider the notion of concurrency optimality and propose the first implementation of a concurrency-optimal binary search tree that intuitively accepts a concurrent schedule if and only if the schedule is correct. Also, we propose parallel combining, a technique that enables efficient implementations of concurrent data structures from their parallel batched counterparts. We validate the proposed techniques via experimental evaluations showing superior or comparable performance with respect to state-of-the-art algorithms. From a more formal perspective, we consider the phenomenon of helping in concurrent data structures. Intuitively, helping is observed when the order of some operation in a linearization is

fixed by a step of another process We show that no wait free linearizable implementation of stack using read write compare swap and fetch add primitives can be help free correcting a mistake in an earlier proof by Censor Hillel et al Finally we propose a simple way to analytically predict the throughput of data structures based on coarse grained locking **Pro .NET**

Apt,Ernst-Rüdiger Olderog,2013-03-09 This book provides a structured introduction to the verification of sequen tial and concurrent programs It thus belongs to the area of programming languages but at the same time it is firmly based on mathematical logic In logic one usually studies fixed syntactic or semantic objects This is not necessarily the case in the area of program verification The objects studied here namely programs do not have a standard syntax their semantics can be defined in many different ways and several approaches to their verification can be contemplated These differences lead to various difficult design decisions Even though we restrict our attention here to one programming style imperative pro gramming we are still confronted with a veritable cornucopia of pro gramming constructs from which an appropriate selection has to be made Having studied some of these constructs separately does not yet imply that we understand their combined effect **Analysis of Synchronization in a Parallel Programming Environment** Rice University.
