Abstract – In this paper, a novel method to synthesize circuits based on threshold logic gates (TLG) is proposed. Synthesis considering TLGs is quite relevant, since threshold logic has been revisited as a promising alternative to conventional CMOS integrated circuits due to its suitability to emerging technologies, such as tunneling diodes, memristors and spintronics devices. A constructive process is applied to generate optimized TLG networks taking into account multiple goals and design costs, including gate count, logic depth and number of interconnections. Experiments carried out over MCNC benchmark circuits have shown an average gate count reduction of circa 32%, reaching up to 54% in some cases, in comparison to related approaches.

Keywords – Digital circuits, logic synthesis, threshold logic, functional composition, threshold networks, TLG.

I. INTRODUCTION

The limits of MOS transistor scaling have motivated investigations about new alternative devices, such as spintronics, resonant tunneling devices (RTD), quantum cellular automata (QCA), single electron transistor (SET) and memristors [1]-[3]. In this new scenario, it has been verified that threshold logic gates (TLG) are more suitable to implement digital integrated circuits (ICs) based on these new technologies, differently from the standard AND/OR based CMOS circuit design [4][5].

However, specific CAD tools must be available for developing TLG based ICs. In this sense, one critical task is to obtain efficient network built using TLGs to implement a specific Boolean function. In [5], Zhang *et al.* proposed a recursive partition of a logic function that is not threshold and merge nodes respecting fan-in restrictions. Unfortunately, the quality of results is very sensitive to the initial Boolean network. On the other hand, the method presented by Subirats *et al.*, in [6], is based on the truth table description of the function. The algorithm compute an ordering of variables using information of on-set and off-set, performing Shannon decomposition up to find threshold logic functions (TLF). However, this approach provides as output a two-level threshold network, without fan-in restriction, being more suitable for neural networks than for IC design. In [7], Gowda *et al.* used a factorized tree to generate a network of threshold gates. The method recursively breaks the given initial expression tree into sub-expressions, identifying sub-tree that are TLFs and assigning the input weights. It is appropriate for IC synthesis using several TLGs, but represents a very time consuming process and presents a strong dependence to the initial expression structure, including the ordering of the initial tree.

In this paper, an algorithm is proposed to synthesize threshold networks aiming to (1) minimize threshold networks taking into account other costs besides threshold gate count, like logic depth and number of interconnections, (2) generate more than one effective solution, considering a design cost order, and (3) eliminate the structural bias dependence in order to improve the quality of results. It is based on a constructive synthesis [8]-[10], which associates simpler sub-solutions with known costs in order to build more complex networks, allowing the optimization of different cost functions other than just the TLG count. The algorithm uses a novel AND/OR association between threshold networks to reduce the total number of TLGs in the circuit.

The rest of this paper is organized as follows. In Section II, some fundamentals are briefly presented for a better understanding of our approach. Section III describes the algorithm proposed to synthesize threshold logic networks. Section IV provides the experimental results, whereas the conclusions are outlined in Section V.

II. PRELIMINARIES

First of all, basic concepts of threshold logic are briefly reviewed for a better understanding of the proposed method.

A. Threshold Logic Gate

Differently from the traditional logic gate design, the threshold logic gate (TLG) implements Boolean function considering weight values for inputs (function variables) and a gate threshold value to be attained. If the sum of weights of activate ('1') inputs is equal to or higher than the given threshold value, then the output logic level of the TLG is high ('1'). Otherwise, the gate output is at low level ('0'). Such operating principle can be expressed as follows:

$$f = \begin{cases} 1 & \text{if } \sum_{i=1}^n w_i x_i \geq T \\ 0 & \text{otherwise} \end{cases} \quad (1)$$

where x_i and w_i represent the logic value and weight of each input, respectively, and T is the threshold value [11].

B. Threshold Logic Function

Threshold logic function (TLF), also called linearly separable function, is a Boolean function that can be implemented into a single TLG. TLF can be completely represented in a compact vector format such as $[w_1, w_2, \dots, w_n; T]$. For instance, the function $f = x_1 x_2 + x_3 x_3$ can be represented as $f = [2, 1, 1; 3]$.
